Searching Heavily Obscured Post-AGB Stars and Planetary Nebulae

I. IRAS Candidates with 2MASS PSC Counterparts

ABSTRACT

Context. The transition from the Asymptotic Giant Branch (AGB) to the planetary nebula (PN) phase is critical in the shaping of PNe. It is suggested that the most asymmetric PNe are the descendant of massive AGB stars. Since these AGB stars are believed to evolve into heavily obscured post-AGB stars and PNe, the compilation of a sample of bona fide obscured post-AGB stars and PNe is important to help understand the formation of asymmetric PNe.

Aims. We aim to identify and characterize in the IR a large number of post-AGB stars and PNe and to assess their degree of optical obscuration. The improved positions will enable future detailed studies to determine their true nature, whereas the optical and IR properties can be used to investigate their spectral behaviour.

Methods. We have used 2MASS, Spitzer GLIMPSE, MSX, and IRAS data in search of the near-IR counterparts of a sample of 165 presumably obscured IRAS post-AGB and PN candidates, and DSS red images to identify the optical counterparts among the objects detected in the near-IR. The IR spectral energy distributions (SEDs) in the wavelength range from 1 μ m to 100 μ m of the sources with unambiguous near-IR counterparts have been analyzed using appropriate colour-colour diagrams.

Results. We have identified the near-IR counterparts of 119 sources out of the 165 IRAS post-AGB and PN candidates in our sample. The improved astrometric coordinates of these sources have allowed us to find optical counterparts for 59 of them, yielding a reduced sample of 60 optically obscured post-AGB star and PN candidates. Among the 119 sources with near-IR counterparts, only 80 have unambiguous identifications in the 2MASS Point Source Catalogue. For these sources, we find that objects with and without optical counterpart, while having similar mid- and far-IR colours, are segregated in colour-colour diagrams that use the near-IR J band to compute one of the colours.

Key words. stars: AGB and post-AGB – stars: evolution – planetary nebulae: general

1. Introduction

Stars of low- and intermediate-mass $(0.8-1~M_{\odot} < M_i < 8-10~M_{\odot})$ experience heavy mass loss episodes during the red giant phase that subsequently intensify at the tip of the asymptotic giant branch (AGB). With typical mass loss rates $10^{-4}-10^{-5}~{\rm M}_{\odot}~{\rm yr}^{-1}$, the AGB wind ejects most of the stellar envelope in a short time, and the star enters the post-AGB phase, from which it evolves into a planetary nebula (PN). The study of objects in the post-AGB phase, the short transition from the AGB to the PN phase, is essential to understand the transformation of a spherically symmetric AGB envelope to an aspherical PN.

Objects in the transition from the AGB to the PN phase are strong far-infrared emitters, making them easily detectable by the Infrared Astronomical Satellite (IRAS). Furthermore, they are located in the [12]-[25] vs. [25]-[60] IRAS two-colour diagram in a well-defined region (van der Veen & Habing 1988). Therefore, the use of the IRAS two-colour diagram provides an invaluable strategy that has resulted in a number of catalogues of young PNe and their im-

mediate precursors, post-AGB stars (e.g. Preite-Martinez 1988; Pottasch et al. 1988; van der Veen et al. 1989; Ratag et al. 1990; Hu et al. 1993; Pereira & Miranda 2007). Recently, Suárez et al. (2006) presented a comprehensive optical spectroscopic atlas of post-AGB stars and young PNe selected from the *IRAS* Point Source Catalogue. In this work, a number of post-AGB candidates were so heavily obscured that no optical counterparts were found, while some others were not observed because they showed signs of strong obscuration in the optical.

Heavily obscured post-AGB stars and PNe represent objects whose circumstellar envelopes have not expanded enough to become optically thin. These objects may descend from the most massive AGB stars, as these are expected to be surrounded by very thick circumstellar envelopes during an important part or all the post-AGB evolution as a result of the large amounts of mass ejected in their envelopes (up to $\sim 6~M_{\odot}$ for a star with initial mass 7 M $_{\odot}$, Bloecker 1995). Moreover, the rapid evolution of the most massive post-AGB stars do not provide sufficient time for the circumstellar envelope to expand and become optically thin. Evidences of this evolutionary path are pro-

^{*} Postdoctoral Research Fellow

vided by young PNe whose very thick envelopes result in extremely high internal extinctions that prevent their detection in the optical (e.g., IRAS 15103-5754, van de Steene & Pottasch 1993; Suárez et al. 2006). Obscured post-AGB stars might be key objects to understand the late evolution of the most massive PN progenitors.

With this work, we start a program devoted to search heavily obscured post-AGB stars and PNe and to characterize them in the IR. The observational material includes data available in the 2MASS database, the MSX catalogue, and the Spitzer Space Telescope GLIMPSE Galactic plane survey, as well as recently acquired more sensitive, higher resolution near-IR observations. In this paper, the first in a series, we use 2MASS, MSX, and Spitzer GLIMPSE data to search for near-IR counterparts of presumably obscured IRAS post-AGB star and PN candidates. The accurate location of the sources with 2MASS counterparts has allowed us to determine whether these sources are really obscured in the optical or not. The 2MASS, MSX, and Spitzer GLIMPSE data have been further used to characterize the near and mid-IR properties of the sources with 2MASS counterparts, allowing us to derive their spectral energy distributions (SED) in the IR domain. In a second paper, we will present new, high-quality near-IR JHK observations in order to search for the near-IR counterparts of the faintest objects, to find the near-IR counterparts of the objects not resolved by 2MASS, to describe the morphology of sources with extended emission, and to investigate the variability of the objects with 2MASS counterparts.

The sample and archival data used in this paper are presented in $\S 2$ and $\S 3$, respectively. The identification of the IRAS sources with their 2MASS counterparts is described in $\S 4$, and their spectral properties are discussed in $\S 5$. Finally, a short summary is given in $\S 6$.

2. The Sample

The sample of IRAS post-AGB star and PN candidates investigated in this work is formed by the objects without optical counterpart in the sample of Suárez et al. (2006), as well as by objects included in the original sample of these authors but not observed because they showed strong indications of heavy obscuration. These IRAS sources fulfill the criteria used by Suárez et al. (2006) in order to select objects with a dust temperature in their envelopes of 80–200 K and an expanding radius of 0.01–0.1 pc. These selection criteria are:

(i) The sources are well detected at 25 and 60 μ m in the IRAS Point Source Catalogue (see Beichman et al. 1988). The flux quality for each band must be:

FQUAL (12
$$\mu$$
m) \geq 1;

FQUAL (25
$$\mu$$
m) = 3;

FQUAL (60
$$\mu$$
m) = 3.

(ii) The ratios between the IRAS photometric fluxes satisfy the following conditions:

$$\frac{F_{\nu} (12 \ \mu\text{m})}{F_{\nu} (25 \ \mu\text{m})} \le 0.50;$$

$$\frac{F_{\nu} \ (25 \ \mu \mathrm{m})}{F_{\nu} \ (60 \ \mu \mathrm{m})} \geq 0.35.$$

vided by young PNe whose very thick envelopes result in extremely high internal extinctions that prevent their detection in the optical (e.g., IRAS 15103-5754, van de Steene (iii) For sources well detected at 100 μ m in the IRAS Point Source Catalogue (FQUAL (100 μ m)=3), it is further imposed:

$$\frac{F_{\nu} (60 \ \mu \text{m})}{F_{\nu} (100 \ \mu \text{m})} \ge 0.60.$$

(iv) The sources must show a low IRAS variability index:

$$VAR \le 60\%$$

The region of the *IRAS* two-colour diagram defined by the previous selection criteria has a small overlap with objects of different nature, mostly young stellar objects, OH stars, symbiotic stars, compact H II regions, and Seyfert galaxies. In particular, the IR SEDs, and thus the IR colours, of the circumstellar material around young stellar objects (e.g. Kenyon & Hartmann 1995) are very similar to these of post-AGB stars and young PNe, making it difficult to discern the nature of nebulae around young and evolved objects. On the contrary, Herbig Ae/Be stars, that exhibit distinct double-peak IR SEDs and are optically bright (e.g. Malfait et al. 1998; Meeus et al. 2001), are not easily mistaken for post-AGB stars and young PNe. To minimize the number of young stellar objects in the sample, two additional criteria have been imposed to our sample:

- (v) The sources are not classified in SIMBAD as young stars.
- (vi) The sources are not located near the boundary of known star forming regions.

With this criteria, the sample of IRAS post-AGB star and young PN candidates being presumably obscured sources consists of the 165 objects listed in Table 1. This table includes the IRAS names, coordinates, and error-ellipse (semi-major and semi-minor axes and position angle of the major axis) of these objects, together with their fluxes and flux quality factors in the IRAS 12 μ m, 25 μ m, 60 μ m, and 100 μ m bands. The typical accuracy of the coordinates of the IRAS sources is \sim 25", ranging from \sim 10" up to 45" for the objects in Tab. 1. The uncertainty in the IRAS coordinates is typically greater along the East-West direction. The location of these objects in the IRAS two-colour diagram is illustrated in Figure 1.

Some of the objects listed in Tab. 1 have been included in previous studies. High-quality images or detailed studies are available for IRAS 15452-5459 (Sahai 2007). IRAS 17150-3224 (the Cotton Candy et al. Kwok, Su. & Hrivnak 1998; Hrivnak et al. Nebula, 2006), IRAS 13356-6249, IRAS 13529-5934, IRAS 15144-5812, IRAS 17009-4154, and IRAS 17088-4221 (van de Steene et al. 2000), and IRAS 17516–2525 and IRAS 18135– 1456 (Siódmiak et al. 2008). Near-IR photometric observations of IRAS 17404-2713, IRAS 17487-1922, IRAS 17516-2525, IRAS 18071-1727, and IRAS 19374+2359 (van der Veen et al. 1989), and spectroscopic observations of IRAS 17540-2753 and IRAS 18135-1456 (Oudmaijer et al. 1995) have also been reported.

3. Archival Data

In order to identify and characterize the near- and mid-IR counterparts of the *IRAS* candidates to post-AGB stars and PNe in our sample, we have searched available 2MASS,

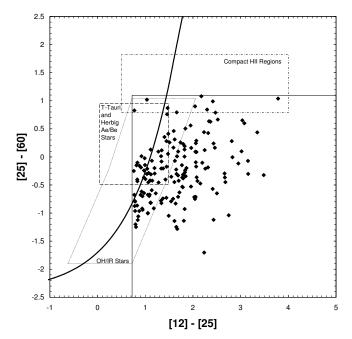

Fig. 1. IRAS colour-colour diagram showing the location of the IRAS sources in our sample. The thin solid lines represent our selection criteria, while the solid thick line represents the expected colours for AGB stars (Bedijn 1987). The loci of OH/IR stars (Sivagnaman 1989; te Lintel Hekkert et al. 1991), T-Tauri and Herbig Ae/Be stars (Harris, Clegg, & Hughes 1988), and compact H II regions (Antonopoulos & Pottasch 1987) that overlap with post-AGB stars and PNe are also overlaid on the diagram. IRAS colours are computed as $[A]-[B]=2.5\log(F_{\nu}(B)/F_{\nu}(A))$.

MSX, and Spitzer GLIMPSE data products. The different properties of these catalogues are described below.

The 2 Microns All Sky Survey (2MASS) provides images of the complete sky in the J (1.25 μ m), H (1.65 μ m), and $K_{\rm S}$ (2.17 μ m) bands (Skrutskie et al. 2006). The image pixel scale is 1" and the typical spatial resolution in the survey was \sim 5", as derived from the FWHM of the stars in the images. The 10 σ detection limit for point-sources is J < 15.8 mag, H < 15.1 mag, and $K_{\rm S} < 14.3$ mag.

The Mid-course Space Experiment (MSX) provides a detailed mid-IR map of a narrow strip, $|b| \leq 5^{\circ}$, of the whole Galactic plane in four different bands, namely band A (8.28 μ m), C (12.13 μ m), D (14.65 μ m), and E (21.3 μ m). The positional uncertainty in the MSX Point Source Catalogue (MSX6C) is of the order of 2", while the spatial resolution is quoted to be 18".3 (Price et al. 2001). The sensitivity levels for the bands A, C, D and E are 160 mJy, 1200 mJy, 1000 mJy and 3000 mJy respectively.

The Galactic Legacy Infrared Midplane Survey Extraordinaire (GLIMPSE) project obtained Spitzer Infrared Array Camera (IRAC) observations of the Galactic plane within the latitude and longitude ranges $|b| \leq 1^{\circ}$, and $|l| = 10^{\circ} - 65^{\circ}$, respectively, in four bands with wavelengths (and bandwidths) 3.550 μ m (0.75 μ m), 4.493 μ m (1.9015 μ m), 5.731 μ m (1.425 μ m), and 7.872 μ m (2.905 μ m). These results were subsequently processed to yield the GLIMPSE Image Atlas with a pointing accuracy of \sim 0".3, and a spatial resolution that varies between 1".7 and 2".0 (Fazio et al. 2004). The sensitivity (saturation levels) for the the different bands are 0.5 mJy (439 mJy) in the 3.6

 μm band, 0.5 mJy (450 mJy) in the 4.5 μm band, 2 mJy (2930 mJy) in the 5.8 μm band, and 5 mJy (1590 mJy) in the 8.0 μm band.

4. Source Identification

The accuracy of the coordinates of an IRAS source may not be good enough to allow a straightforward identification of its counterpart in the 2MASS, MSX or GLIMPSE catalogues. This is especially the case of IRAS sources in crowded fields located along the Galactic plane or near the Galactic Center, for which the error-ellipse typically includes several near-IR sources. In order to define a strategy to search for the near- and mid-IR counterparts of the IRAS sources in Tab. 1, a comparison between the three databases used in this work can be useful.

The 2MASS images provide a complete coverage of the sky with a spatial resolution ($\sim 5''$) better than the positional uncertainty of the IRAS sources in Tab. 1. However, the sensitivity of the 2MASS images to obscured sources is limited because of the large extinction and intrinsic red colours of these sources. Accordingly, the identification of the 2MASS counterparts of the IRAS sources in our sample is not obvious in general. This is not the case of the GLIMPSE Image Atlas that has a high sensitivity to mid-IR sources and provides better spatial resolution ($\leq 2''(0)$) than the MSX and 2MASS images. This database thus seems especially suited to determine with a great accuracy the position of the *IRAS* sources in Tab. 1. Unfortunately, its limited spatial coverage results in a reduced number of sources with available GLIMPSE data. On the other hand, the MSX data have an extremely good sensitivity to obscured sources and its coverage is sufficiently good to include a significant fraction of the sources in our sample. The MSX images, however, have a poor spatial resolution (\sim 18") that can make difficult to pinpoint the near-IR counterpart.

Given the different properties of the 2MASS, MSX, and GLIMPSE Image Atlas, we have proceed as follows in order to identify the near-IR counterparts of the IRAS sources. When available, we have first examined the GLIMPSE images to pinpoint the accurate location of the IRAS sources, thus allowing us to find its near-IR counterpart in 2MASS images. This procedure is illustrated in Figure 2 for IRAS 17359–2902; the bright Spitzer mid-IR source inside its IRAS error-ellipse allows the unambiguous identification of its near-IR counterpart among the near-IR sources within this ellipse in the 2MASS image. The use of the GLIMPSE images resulted in the identification of the near-IR counterparts of 22 sources in Tab. 1, although it must be noticed that some heavily obscured *Spitzer* sources were not detected in the 2MASS images and are not listed in Tab. 1. We then examined the MSX data of the sources with no GLIMPSE data available and were able to find the near-IR counterparts for 52 additional sources in Tab. 1. A typical example of the identification of the near-IR counterpart of an IRAS source using MSX data is shown in Figure 2 for IRAS 17010-3810; the position of the MSX source MSX6C G347.4963+01.8505, coincident within 1''with the position of the source 2MASS 17042731-3814417 (marked in the 2MASS image), has allowed us to determine that this is the near-IR counterpart of IRAS 17010-3810. Finally, we have examined the JHK 2MASS images of the IRAS sources with no GLIMPSE and MSX data available, and selected the near-IR counterparts that appear as isolated sources within the error-ellipse of the IRAS source and whose near-IR colours are typical of post-AGB stars or PNe, i.e., $(J-H)\sim 1.0\,$ and $(H-K)\sim 0.4\,$ (García-Lario et al. 1997). This has added an additional number of 43 IRAS sources with 2MASS counterparts. The result is a total of 119 sources with near-IR emission out of the sample of 165 sources listed in Tab. 1.

Among these 119 *IRAS* sources detected in the near-IR, there are 80 sources with a reliable counterpart in the 2MASS Point Source Catalogue (PSC). The remaining 39 *IRAS* sources in Tab. 1 have near-IR emission detected in 2MASS, but the assignation of a counterpart in the 2MASS PSC is dubious due either to their extended appearance in the 2MASS images, to the possible contamination by an adjacent source, or to their extreme faintness, at the detection limit of 2MASS.

The sample of the 80 IRAS post-AGB and PN candidates in Tab. 1 with a counterpart in the 2MASS PSC is listed in Table 2 with their coordinates and near-IR magnitudes, and their identification charts are shown in Figure 3. The angular separation with the position of the IRAS source is also listed in this table. The distance between the IRAS and 2MASS coordinates is typically below 5", i.e., within the ellipse-error of the IRAS coordinates, with no preferential direction of the distance vector. In a few cases, the offset between the IRAS and 2MASS coordinates is larger than the IRAS coordinates uncertainty. Obviously, these are sources that have been identified through their GLIMPSE Spitzer or MSX images. A close inspection to the original IRAS images reveals that these sources are either extended sources or mutiple, unresolved sources, thus introducing a significant offset in their IRAS coordinates.

The sample of the 39 *IRAS* post-AGB and PN candidates in Tab. 1 with a 2MASS counterpart but dubious assignation in the 2MASS PSC are listed in Table 3 and their identification charts are shown in Figure. 4.

Finally, the 46 sources that do not have a 2MASS counterpart are listed in Table 4. Most of these sources have been observed by MSX and many of them have even Spitzer GLIMPSE observations, but no near-IR counterpart is detected in 2MASS at the improved astrometric positions provided by the MSX and Spitzer GLIMPSE catalogues. Only IRAS 16245–3859, IRAS 18385+1350, and IRAS 21537+6435 have no Spitzer GLIMPSE nor MSX observations, and they do not have an obvious near-IR counterpart in 2MASS images within their IRAS ellipse-error. The study of sources in Tab. 3 and 4 requires near-IR observations of greater spatial resolution and sensitivity, respectively, than the 2MASS observations used in this paper. These observations will be presented in a subsequent paper.

5. Discussion

5.1. Degree of Obscuration Among the IRAS Sources

Using the improved accuracy of the 2MASS coordinates, we have searched for the optical counterpart of the sources in Tab. 2 and 3 in the red plates of the Digitized Sky Survey¹ (DSS). The information on the optical detection of these

sources, added to Tab. 2 and 3, unveils a significant population of optical counterparts for the a priori supposedly heavily obscured IRAS post-AGB and PN candidates. Out of the 119 objects with 2MASS counterpart, 59 have an optical counterpart, i.e., only 50% of the objects in these two tables can be considered optically obscured.

Despite the limited spatial resolution and sensitivity of the 2MASS images and, very notably, of the DSS red images, the homogeneity of these two databases grants a brightness limited search that is meaningful for a statistical analysis. Therefore, the simple detection of an IRAS source in our sample in the DSS and/or 2MASS images allows us to determine the degree of obscuration of this source. Accordingly, we can define three types of sources based on the shortest wavelength at which they are detected:

- Type m sources (for mid-IR): Heavily obscured sources that are neither detected in DSS red images, nor in the 2MASS images.
- Type n sources (for near-IR): Optically obscured sources detected in 2MASS images, but not in DSS images.
- Type o sources (for optical): Sources with little optical and near-IR obscuration detected both in DSS and 2MASS images.

Type m sources will be found among the sources listed in Tab. 4. The study of these sources will be postponed to an upcoming paper. Similarly, the 2MASS spatial resolution has not allowed us to measure the JHK magnitudes of sources in Tab. 3 and the study of this sources will also be deferred. In the following, we will focus on the sources listed in Tab. 2, i.e., the sources of types n and o with a near-IR counterpart in the 2MASS PSC.

5.2. Spectral Properties

The near- and mid-IR properties of the type o and type n sources can be used to investigate their nature. Using the JHK magnitudes of the sources listed in Tab. 2, the MSX and Spitzer GLIMPSE fluxes given in Table 5, and their IRAS fluxes (Tab. 1), we have built the IR spectral energy distributions (SEDs) that are shown in Fig. 3. The analysis of the IR SEDs of these sources can be performed by studying the different colour diagrams shown in Figures 5, 6, and 7.

The J-H vs. $H-K_s$ colour diagram (Fig. 5) shows that the sources in this sample have near-IR colours mostly in the ranges 0.5 < J-H < 3 and $0.2 < H-K_s < 3$, although a few sources are very highly obscured, with $H-K_s$ colours up to ~ 5 mag. In this diagram, sources detected in the optical tend to have smaller values of their J-H and $H-K_s$ colours, with almost all these sources having J-H < 1.6 and $H-K_s < 1.4$. This trend is more clearly seen in the $J-K_s$ vs. H diagram (Fig. 5) that shows noticeable differences

the UK Science and Engineering Research Council, until 1988 June, and thereafter by the Anglo-Australian Observatory. The Palomar Observatory Sky Survey was funded by the National Geographic Society. The Oschin Schmidt Telescope is operated by the California Institute of Technology and Palomar Observatory. The plates were processed into the present compressed digital form with the permission of these institutes. The Digitized Sky Survey was produced at the Space Telescope Science Institute under US government grant NAGW-2166.

¹ The Digitized Sky Survey is based on photographic data obtained using the UK Schmidt Telescope and the Oschin Schmidt Telescope on Palomar Mountain. The UK Schmidt was operate by the Royal Observatory of Edinburgh, with funding from

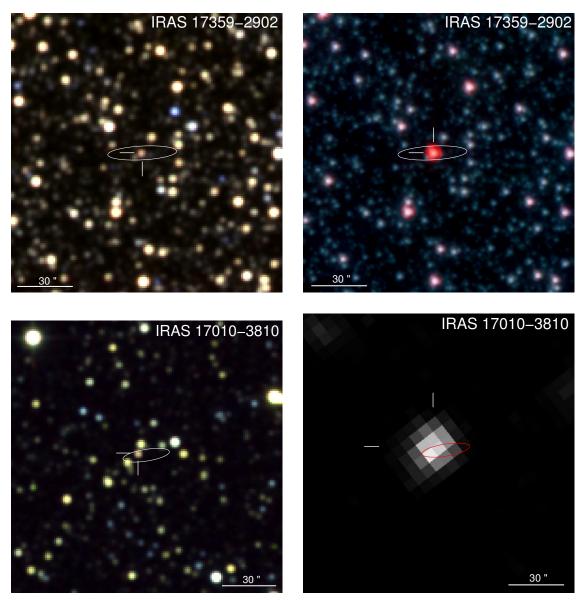

Fig. 2. Representative examples of objects whose near-IR counterparts have been identified using Spitzer GLIMPSE or MSX data. (top) 2MASS J (blue), H (green), and $K_{\rm S}$ (red) composite picture (left) and Spitzer GLIMPSE 3.6 μ m (blue), 4.5 μ m (green), and 8.0 μ m (red) composite picture (right) of IRAS 17359–2902. (bottom) 2MASS J (blue), H (green), and $K_{\rm S}$ (red) composite picture (left) and MSX image in the 8.28 μ m A band (right) of IRAS 17010–3810. The locations of the near-IR counterparts and the IRAS ellipse-error are overlaid. North is up, east to the left.

in the distribution of sources of types o and n; type o sources are mostly located on the band $1 < J - K_s < 2.5$, while type n sources are located mostly above this band, with $J - K_s \ge 2.5$. The interpretation of this behaviour is clearly illustrated by the SED of these two types of sources: type o sources use to have flat or shallow near-IR SEDs (e.g., IRAS 14521-5300), while type n sources usually present steep near-IR SEDs (e.g., IRAS 14104-5819).

The segregation between the sources of type o and n with 2MASS PSC counterpart is also clear in the MSX-J colour diagram (Fig. 6). In this diagram, sources of type o have J-[8.3] colours typically lower than 10. On the contrary, sources of type o and n are not separated in the MSX colour-colour diagram (Fig. 6) on which both types are spread over a wide region. Interestingly, these sources are mostly located in the quadrants of this diagram that have been suggested to be populated by AGB and post-AGB

stars, while generally avoiding the quadrant on which objects in star forming regions are typically found (Sevenster 2002). This result confirms our selection criteria for AGB and post-AGB stars in $\S 2$.

Similarly, the IRAS colour-colour diagram shown in Fig. 7 does not single out the optical type o sources from the near-IR type n sources in Tab. 2. On the other hand, the two types of sources show different properties in the K_s –[8.3] vs. J–[25] colour-colour diagram (Fig. 7). In this diagram (spotlighted by Suárez et al., in prep., as able to discriminate very efficiently between different types of SEDs of post-AGB stars), sources of type o have mostly J–[25]<7 and sources of type n have J–[25]>9.6, with an intermediate region populated by both type o and n sources. It is interesting to note that the K_s –[8.3] and J–[25] colours of the sources in our sample are clearly correlated.

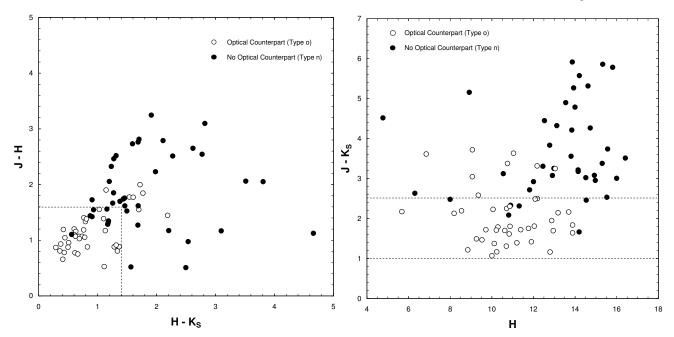

Fig. 5. (left) J-H vs. $H-K_s$ and (right) $J-K_s$ vs. H 2MASS diagrams of the IRAS post-AGB star and PN candidates in our sample with 2MASS PSC counterparts. The dashed lines mark the regions mostly occupied by sources of type o (sources with optical counterpart).

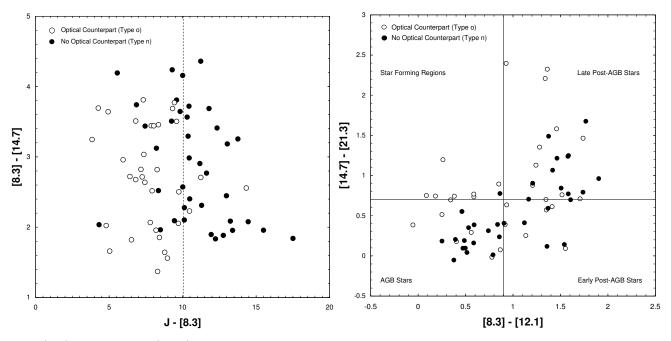

Fig. 6. (left) MSX-J and (right) MSX colour-colour diagrams of the IRAS post-AGB star and PN candidates with 2MASS PSC and MSX counterparts. The vertical line in the MSX-J colour-colour diagram at J-[8.3]=10 marks a rough division between sources of type o and n. The vertical and horizontal lines in the MSX colour-colour diagram divide it into four quadrants that correspond to areas of higher probability of containing the different types of objects labeled on the diagram (Sevenster 2002).

In all the colour-colour diagrams shown in Figs. 5, 6, and 7, the use of colours in which the J magnitude is involved has allowed us to separate the sources with optical counterpart from these obscured in the optical. It can be concluded that the relation between the magnitude in the J band and in different bands in the near-, mid-, and far-IR is critical in order to forecast the level of emission at optical wavelenghts.

5.3. Sources in the Spitzer GLIMPSE Image Atlas

The Spitzer images of the IRAS post-AGB star and PN candidates with 2MASS PSC counterparts that are available in the GLIMPSE Image Atlas are presented in Figure 8. All IRAS sources identified in the Spitzer GLIMPSE Image Atlas are point-like, except IRAS 18229-1127, IRAS 18454+0001, and IRAS 18576+0341, whose PSFs have FWHMs broader

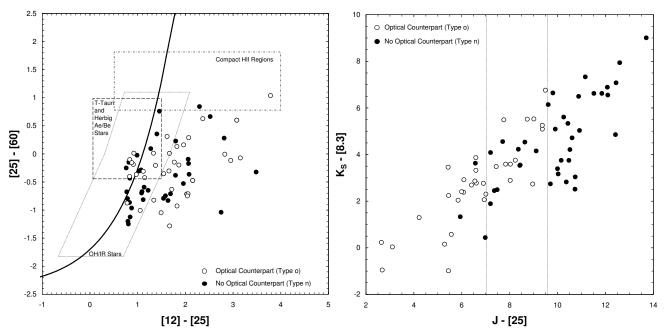

Fig. 7. (left) IRAS and (right) K_s –[8.3] vs. J–[25] colour-colour diagrams of the IRAS post-AGB star and PN candidates with 2MASS PSC and MSX counterparts. In the IRAS colour-colour diagram, the locii of OH/IR stars, T-Tauri and Herbig Ae/Be stars, and compact H II are overlaid as in Fig 1. The vertical lines in the K_s –[8.3] vs. J–[25] diagram mark three regions with the leftmost being dominated by sources with optical counterpart (type o sources), and the rightmost being exclusively populated by sources with no optical counterpart (type o sources).

than those of point sources in their respective images. IRAS 18229–1127 has a FWHM of 3"0 in the 4 IRAC bands, just above the FWHM of stellar sources (~2"1). IRAS 18454+0001 is a point-like source, except in the 8 μ m band, with a FWHM of 2"4 (compared to the FWHM of 1"9 of stellar sources). Finally, IRAS 18576+0341 has the broadest FWHM, ~5"0 (the FWHM of stellar sources is ~2"0), in the 3.6 μ m, 4.5 μ m, and 5.8 μ m bands (its image in the 8 μ m band is saturated).

6. Summary

Using 2MASS, Spitzer GLIMPSE, and MSX data products, we have identified 119 near-IR counterparts out of a sample of 165 IRAS post-AGB star and PN candidates. For these sources, we provide near-IR identification charts. Among these 119 sources with near-IR counterpart, 80 objects have unambiguous 2MASS PSC counterpart. For these sources, we further provide improved coordinates, and IR energy spectral distributions from 1 μ m to 100 μ m.

Using the improved coordinates of the sources with 2MASS PSC counterpart, we have searched for their optical counterparts in DSS red plates and found that $\sim 50\%$ of these sources are detected in the optical. We have then investigated the different spectral properties of the sources with and without optical counterpart, dubbed sources of type o and n, respectively. The two types of sources have similar mid- and far-IR colours, but they appear clearly segregated in colour-colour diagrams in which the magnitude in the J band is used to compute one of the colours.

Acknowledgements. This publication makes use of data products from the 2MASS, which is a joint project of the University of Massachusetts and the Infrared Processing and Analysis Center/California Institute of Technology, funded by the National

Aeronautics and Space Administration and the National Science Foundation.

This work is based, in part, on observations made with the *Spitzer* Space Telescope, which is operated by the Jet Propulsion Laboratory, California Institute of Technology under a contract with NASA. Support for this work was provided by an award issued by JPL/Caltech. GRL acknowledges support of a postdoctoral fellowship from CONACyT (Mexico) grant 75861.

MAG, OS, LFM, and JFG acknowledge support from Consejería de Innovación, Ciencia y Empresa of Junta de Andalucía. GRL, MAG, and LFM are partially funded by grant AYA2005-01495 of the Spanish Ministerio de Educación y Ciencia (MEC). JFG is partially funded by grant 2005-08523-C03-03 of MEC. GRL, MAG, OS, and LFM are partially funded by grant AYA2008-01934 of the Spanish Ministerio de Ciencia e Innovación (MICINN). OS and JFG are partially funded by grant 2008-06189-C03-01 of MICINN.

This research has made use of the SIMBAD database, operated at CDS, Strasbourg, France.

[†] The IRAS flux quality factor, FQUAL, indicates whether the flux values are of high quality (3), moderate quality (2), or simply represent an upper limit of the flux (1). The four values in this column refer consecutively to the flux quality in the 12 μ m, 25 μ m, 60 μ m, and 100 μ m bands.

Table 2. IRAS Post-AGB Star and PN Candidates with Near-IR Counterparts in the 2MASS PSC.

Table 3. IRAS Post-AGB Star and PN Candidates with no Counterparts in the 2MASS PSC.

Object	Optical	Comments
IRAS 04137+7016	Yes	Two objects unresolved by 2MASS.
IRAS 05573 + 3156	No	Diffuse emission.
IRAS 06499 + 0145	Yes	Diffuse emission.
IRAS 11381 - 6401	Yes	Two objects unresolved by 2MASS.
IRAS 11544 - 6408	Yes	Source very faint. 2MASS magnitudes not available.
IRAS 12360 - 5740	Yes	2MASS magnitudes contaminated by a nearby star.
IRAS 12405 - 6219	No	Diffuse emission or multiple objects unresolved by 2MASS.
IRAS 13293 - 6000	No	Two objects unresolved by 2MASS.
IRAS 13427 - 6531	Yes	Multiple objects unresolved by 2MASS.
IRAS 13529 - 5934	Yes	Two objects unresolved by 2MASS.
IRAS $14249 - 5310$	No	Two objects unresolved by 2MASS.
IRAS 15103 - 5754	No	Diffuse emission.
IRAS 15229 - 5433	Yes	Diffuse emission or multiple objects unresolved by 2MASS.
IRAS 15452 - 5459	No	Diffuse emission.
IRAS 15534 - 5422	Yes	Diffuse emission.
IRAS $16209 - 4714$	Yes	2MASS magnitudes contaminated by a nearby star.
IRAS 16296 - 4507	Yes	Diffuse emission or two objects unresolved by 2MASS.
IRAS $16333 - 4807$	No	Diffuse emission.
IRAS $16507 - 4810$	Yes	Diffuse emission or two objects unresolved by 2MASS.
IRAS 17009 - 4154	No	Diffuse emission.
IRAS $17052 - 3245$	No	Source very faint. 2MASS magnitudes not available.
IRAS $17150 - 3224$	Yes	Diffuse emission, the Cotton Candy Nebula.
IRAS $17234 - 4008$	No	Two objects unresolved by 2MASS.
IRAS $17269 - 2235$	Yes	Two objects unresolved by 2MASS.
IRAS 17301 - 2538	Yes	Two objects unresolved by 2MASS.
IRAS 17361 - 4159	No	Two objects unresolved by 2MASS.
IRAS $17376 - 3448$	No	Diffuse emission or multiple objects unresolved by 2MASS.
IRAS $17418 - 3335$	No	Two objects unresolved by 2MASS.
IRAS $17479 - 3032$	No	Two objects unresolved by 2MASS.
IRAS $17487 - 1922$	Yes	Two objects unresolved by 2MASS.
IRAS $17506 - 2955$	No	Two objects unresolved by 2MASS.
IRAS 17560 - 2027	Yes	Two objects unresolved by 2MASS.
IRAS $18087 - 1440$	No	Two objects unresolved by 2MASS.
IRAS 19015 + 1256	No	Two objects unresolved by 2MASS.
IRAS $19071 + 0857$	No	Diffuse emission or multiple objects unresolved by 2MASS.
IRAS 19178+1206	No	Two objects unresolved by 2MASS.
IRAS 19208+1541	No	Two objects unresolved by 2MASS.
IRAS $20035 + 3242$	No	Two objects unresolved by 2MASS.
IRAS 21554+6204	No	Two objects unresolved by 2MASS.

- Fig. 3. (left) 2MASS J (blue), H (green), and $K_{\rm S}$ (red) composite pictures and (right) IR spectral energy distributions (SEDs) of the IRAS post-AGB star and PN candidates with near-IR counterparts in the 2MASS PSC. In the pictures, north is up, east to the left, and the locations of the near-IR counterparts and their type (o or n whether they are detected in DSS red images or not) are overlaid. The SEDs are built using data extracted from the 2MASS, Spitzer GLIMPSE, MSX, and IRAS catalogues. The arrows at 100 μ m represent flux upper limits (IRAS quality factor, FQUAL, equals to 1).
- **Fig. 4.** 2MASS J (blue), H (green), and $K_{\rm S}$ (red) composite pictures of the IRAS post-AGB star and PN candidates with near-IR counterparts that are not resolved or clearly detected in the 2MASS PSC. The locations of the near-IR counterparts and their type (o or n whether they are detected in DSS red images or not) are overlaid on the pictures. North is up, east to the left.
- Fig. 8. Spitzer GLIMPSE composite pictures of the IRAS post-AGB star and PN candidates with near-IR counterparts in the 2MASS PSC and Spitzer observations. The blue, green, and red colours in the composite pictures correspond to the 3.6 μ m, 4.5 μ m, and 8.0 μ m bands, respectively, except for the pictures of IRAS 13421-6125, IRAS 15408-5413, IRAS 19374+2359, and IRAS 18576+0341 where they represent the 3.6 μ m, 4.5 μ m, and 5.8 μ m bands, respectively, and for the picture of IRAS 17548-2753 where the 4.5 μ m band is shown in blue and green, and the 8.0 μ m band is shown in red. The locations of the sources are overlaid on the pictures. North is up, east to the left.
